ABSTRACT

Self-powered wearable sensor nodes are promising to be used in various healthcare applications in near future. However, several design challenges exist before their wide usage, such as limited and unstable power output as well as the unpredictable power profiles. This paper provides an overview of emerging techniques to attack those challenges and argues that cross-layer optimizations should be adopted.

1. INTRODUCTION

Modern wearable sensor nodes deployed on human bodies are promising to have great potentials in a broad range of healthcare applications. However, the limited operating time and frequent maintenance make the batteries become as a critical obstacle to be widely deployed. Recently, energy harvesting techniques are proposed to relieve those problems [1], and self-powered sensor nodes are attracting more and more attentions.

2. DESIGN CHALLENGES

A typical self-powered wearable sensor node consists of power supply system and computation system. The former harvests energy from ambient power sources, such as solar, vibration, temperature difference and RF energy, and the harvested power is converted into a proper level by a voltage regulator to charge an energy buffer and power the computation system. The latter performs information sensing, processing and transmitting. Instead of advantages from energy harvesting techniques, several major design challenges exist: 1) *Limited output power:* The typical generated power ranges from several μW to hundreds of μW, which is magnitudes smaller than the consumption of mainstream low power chips. 2) *Frequent power failures:* Lots of power failures occur frequently in self-powered systems, which operate in an energy intermittent mode. 3) *Hard to predict:* The power profiles are determined by the ambient factors, which are hard to be predicted and affect the system performance.

3. RESEARCH OPPORTUNITIES

Several emerging techniques are promising to mitigate the problems in self-powered wearable sensors. First, near-threshold circuits [2], power gating [3] and nonvolatile memory [4] techniques can be used to fill the aforementioned gap by reducing dynamic and leakage power. Furthermore, simultaneous optimization of power supply and computation should be considered, because the mismatch between harvesting and consuming significantly affects the overall system efficiency. Second, circuit, architecture and software solutions should be developed to tolerate power failures, and nonvolatile processors [5] are one of such promising techniques. What's more, reliability issues, e.g. data inconsistency [6], is another problem in the energy intermittent system. Finally, as variations of power profiles introduce big uncertainty to the performance, power profiles should be added into traditional real-time scheduling techniques to guarantee the QoS requirement [7], where more advanced predicting methods are needed for energy harvesting.

4. CONCLUSION

Self-powered wearable sensor nodes have manifested strong vitality. However, the harvested power is limited, unstable and hard to predict, which prevents their wide utilization. This paper illustrates the unique challenges arising from such systems and lists the emerging techniques for those problems. We believe that cross-layer optimization opportunities from circuit to software exist for self-power wearable sensors, which is a promising research direction in future.

5. ADDITIONAL AUTHORS AND THANKS

Additional authors: Daming Zhang (Tsinghua University, email: `zdm06@mails.tsinghua.edu.cn`), Kaisheng Ma (Pennsylvania State University, email: `jkaishengma@icloud.com`), Zewei Li (Tsinghua University, email: `lizw007@126.com`), Yinan Sun (Tsinghua University, email: `syn08@mails.tsinghua.edu.cn`). This work was supported in part by 863 Program under contract 2013AA013201, NSFC under grant 61202072, Huawei Shannon Lab, the Importation and Development of High-Caliber Talents Project of Beijing Municipal Institutions under contract YETP0102.
